

Wack's Wicked Plants

Carnivorous Plants

Drosera (Sundew) - Care leaflet

Summer

- > Full, direct sunshine, in- or outdoors
- > Rainwater only, sit in water (in a deep saucer)
- > You cannot overwater the plant in summer
- > Feeding: we have never found this to be necessary, as the plants only require a few insects per year to survive. If you are worried, stick the plant outside on a sunny day and watch it go to work

Winter

- > We recommend a cool, airy, light area. *Drosera capensis*, *capensis alba*, *nidiformis*, *aliciae*, *madagascariensis*, *spatulata* are not hardy, will take down to 0 °C. Hardy sundews (*Drosera binata*, *filiformis*) are best kept in a cold greenhouse or polytunnel. Native sundews (*Drosera rotundifolia*, *anglica*, *intermedia*) can be grown outside.
- > The plants will have a dormancy period, which can vary from just a few leaves browning/crisping, to everything dying back – remove all brown bits. Hardy sundews will form a winter bud.
- > During dormancy, the main risk to the plant is rotting caused by fungal diseases, usually a result of overwatering. Reduce watering, keeping the plant damp, but never let them dry out completely. This is not usually an issue if the plant is outdoors.

Rainwater alternatives: distilled, de-ionised, reverse osmosis water

Repotting: when the plant is bursting out of its pot, in a specific peat and perlite mixture or specialist peat free mix (both available from our on line shop). Best time for repotting and splitting (if you want) is early spring.

Seeds: Keep refrigerated, sow from March onwards frost free, on top of the peat/perlite mixture, do not cover, sit in rainwater in full sun.

We highly recommend you research your plants on the internet for more detailed information, or look on:
